CHAPTER 1

USING THE SAMPLE CONSTRUCTION SCENARIOS

Introduction
Background
Collection of Additional Information
Sample Construction Scenarios

INTRODUCTION

In accordance with South Coast Air Quality Management District (SCAQMD) Governing Board's direction, staff has developed the localized significance threshold (LST) methodology and mass rate look-up tables, which were formally adopted by the Governing Board on October 3, 2003 for voluntary use by other public agencies. The mass rate LST look-up tables are only applicable to the following criteria pollutants: oxides of nitrogen (NO_X), carbon monoxide (CO), and particulate matter less than 10 microns in aerodynamic diameter (PM10). The mass rate look-up tables were developed for each source receptor area (SRA) and can be used on a voluntary basis by public agencies to determine whether or not a project may generate significant adverse localized air quality impacts. LSTs represent the maximum emissions from a project that are not expected to cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standards, and are developed based on the ambient concentrations of that pollutant for each source receptor area. For PM10 LSTs, mass rate look-up tables were derived based on requirements in SCAQMD Rule 403 – Fugitive Dust.

Intended Use of LSTs by Local Public Agencies

The use of LSTs is voluntary, to be implemented at the discretion of local public agencies acting as a lead agencies pursuant to the California Environmental Quality Act (CEQA) or the National Environmental Policy Act (NEPA). Detailed information on the methodology used to derive the mass rate LST look-up tables can be viewed at the following SCAQMD website address: http://www.aqmd.gov/hb/031034a.html.

LSTs Applicability

LSTs would only apply to projects that must undergo an environmental analysis pursuant to CEQA or the National Environmental Policy Act (NEPA). Projects that are statutorily or categorically exempt under CEQA would not be subject to LST analyses. Projects exempt from CEQA also include infill projects that meet the H&S Code provisions or projects identified by lead agencies as ministerial. The methodology and screening tables have been prepared to be included as an appendix to the SCAQMD CEQA Air Quality Handbook (Handbook).

Mass rate LST Look-Up Tables Applicability

The mass rate LST look-up tables apply only to projects that are less than or equal to five acres. Lead agencies may use the mass rate LST look-up tables to determine localized air quality impacts or use the LST mass look-up tables as a screening tool. If the project exceeds any applicable LST when the mass rate look-up tables are used in a screening analysis, then project specific air quality modeling may be performed. In the event that the project area exceeds five acres, it is recommended that lead agencies perform project-specific air quality modeling for these larger projects.

PM10 LSTs were derived based on concentration requirements in Rule 403 – Fugitive Dust, and tend to be more limiting than the CO or NOx LSTs. The Handbook, however, identifies a substantial number of PM10 (fugitive dust) mitigation measures that may be used to mitigate project PM10 emissions to less than the relevant PM10 mass rate LST. In general, LSTs are derived based on the location of the activity (i.e., the SRA); the project emission rates of NO_X, CO, and PM10; and the distance to the nearest exposed individual. The location of the activity and the distance to the nearest exposed individual can be determined by maps, aerial and site

photos, or site visits. To calculate NOx, CO, and PM10 emissions, the methodologies, emission factors and/or rates identified in the *Handbook* may be used (see Chapter 9 and the Appendix to Chapter 9). Relative to construction, the lead agency may use the sample construction scenarios described in the following sections. If lead agencies use the mass rate LST look-up tables and determine that the proposed project under consideration exceeds any applicable LST, they may choose to apply any of the substantial number of applicable mitigation measures identified in Chapter 11 of the *Handbook* to the proposed projects (see Appendix H).

Format and Use of This Document

This document is intended to provide local lead agencies with the information necessary to perform a localized air quality analysis. The format of this document consists of the following.

Chapter 1

- Introduction
- Background contains information on the development of the LSTs.
- The Pilot Study describes the pilot study that was conducted to develop more accurate sample construction scenarios. The actual sample construction scenarios can be found in Appendices A through E.
- Sample Construction Scenarios explains the three ways that the construction scenarios can
 be use by lead agencies, which include using the sample construction scenarios to represent
 the proposed project, using the sample construction scenario spreadsheets as a template or
 basis to prepare project-specific analyses, or using a combination of those approaches for
 various proposed project phases.

Chapter 2

Applying the Sample Construction Scenarios - this chapter provides guidance for applying
the sample construction scenarios to specific projects when the projects do not conform
exactly to the characteristics of the applicable sample construction scenario.

Appendices

- Appendices A through E contain each individual sample construction scenario, one through five acres, respectively.
- Appendix F provides the sources of emission factors and emission calculation methodologies.
- Appendix G provides simplified off-road emission factors to assist planners with calculating construction equipment emissions.
- Appendix H contains a list of mitigation measures and control efficiencies from the SCAQMD's *CEQA Air Quality Handbook* to assist planners with identifying measures to mitigate impacts from a project.
- Appendix I contains a table that allows planners to identify the source receptor area of their
 proposed project from the city where the proposed project would be located. The source
 receptor area is used to identify which LST from the mass rate LST look-up tables is
 applicable to the proposed project.
- Appendix J details how to scale mass rate LSTs for proposed projects with plot sizes that are in between the plot sizes in the mass rate LST look-up tables.

• Appendix K - contains the mass rate look-up tables for proposed project site between one and five acres for each source receptor area.

BACKGROUND

The LST methodology is applicable to projects where emission sources occupy a fixed location. This means that the LST methodology will apply to projects during construction because, although construction equipment may move around the construction site, their movements are restricted to a fixed location. The LST methodology would typically not apply to the operational phase of project because emissions are primarily generated by mobile sources traveling on local roadways over potentially large distances or areas. LSTs would apply to the operational phase of a project, if the project includes stationary sources or attracts mobile sources that may spend long periods queuing and idling at the site. For example, the LST methodology could apply to projects such as warehouse/transfer facilities.

During development of the LST methodology and mass rate look-up tables, SCAQMD staff received comments stating that using the LSTs may require a more detailed analysis of air quality impacts than are currently prepared. As a result, local planners requested guidance on setting up construction scenarios and assistance with calculating construction air quality impacts in addition to using the methodologies in the *Handbook*.

In response to this request, in October 2003 SCAQMD staff developed three sample construction scenarios, one-acre, two-acre, and five-acre in size, where construction impacts do not exceed the most stringent LSTs. The sample scenarios were designed to be used by local lead agencies as models or templates for analyzing construction air quality impacts for projects undergoing an environmental analysis under CEQA or the National Environmental Policy Act NEPA.

At the October 3, 2003 Governing Board Hearing, SCAQMD staff presented the LST methodology, mass rate look-up tables, and the sample construction scenarios to the Governing Board for consideration. The Governing Board adopted the LST methodology¹ pursuant to CEQA Guidelines Section 15064.7. However, in the adopting resolution, the Governing Board directed staff to conduct a nine-month phase-in period for field testing. The objective of the field testing was to conduct a pilot program with cities and local contractors to assess any potential implementation issues and report to the SCAQMD's Mobile Source Committee, at which time the Mobile Source Committee would formally approve complete implementation of the LST methodology or provide further direction. Staff was also asked to expand the list of sample construction scenarios to reduce resource impacts to local government and contractors by streamlining the construction analysis, updating mitigation measures with notations as to the appropriateness of specific measures for projects of different sizes, and reconvening the working group to review the results of the field testing and evaluate refinements or improvements needed to further simplify use of the LST methodology for local lead agencies.

_

¹ It should be noted that the action taken by the Governing Board was to adopt the LST methodology. The reason for adopting the methodology rather than the mass rate look-up tables is that the mass rate look-up tables for CO and NOx are based on ambient concentrations. Because monitored ambient concentrations change from year to year, the mass rate look-up tables must be modified annually to reflect the most recent three years of monitored data. This approach allows staff to update the mass rate emission tables without approval from the Governing Board. Governing Board approval is required if the LST methodology is modified.

COLLECTION OF ADDITIONAL INFORMATION

In order to improve the construction scenarios additional information that characterize typical construction site equipment and activities was required. To this end, SCAQMD staff conducted a construction site survey and updated off-road and on-road emission factors. SCAQMD staff worked with construction and building industries to develop a questionnaire for use at construction sites to gather accurate information to better estimate emissions from construction equipment based on their typical operations for projects less than five acres. The SCAQMD hired a consultant to conduct construction site surveys throughout the Basin. The consultant surveyed approximately 50 construction sites and compiled information on the various construction phases including demolition, site preparation, construction of structures, etc. This information was compiled, analyzed, and used to develop conservative emission estimates from "typical" construction site scenarios for five sample construction scenarios based on area: one-, two-, three-, four-, and five-acre project areas. Types of construction projects surveyed included schools, churches, libraries, retail establishments, restaurants, service stations, office buildings, warehouses, storage facilities, hotels, and multiple family dwellings (Table 1).

Table 1
Typical Types of Projects by Size (Area)

| One-acre | Two-acre | Three-acre |
|--|--|---|
| o Restaurant | o Commercial Office Buildings | o Reconstruction of Street |
| o Church | Retail Garden Center | Residential Subdivision |
| Education Center | Public Library | Multi-story Apartments |
| Office and Warehouse | Condominiums | o Bank |
| Supermarket | o Hotel | o Hotel |
| Single and Multi-Family Dwelling | Single and Multi-Family Dwelling | o Multi-story Offices |
| | o Remodel Classrooms | o College |
| | o Multi-story Worship Center | Storage Facility |
| | o Retail Department Store | Car Dealership |
| | o Retail Shopping Center | _ |
| | o Restaurant | |
| | Multi-story Self Storage | |
| | Tenant Improvement | |

Note: Four- and five-acre projects would include the same types of projects identified in the table under two- and three-acre project types.

Based on the results of the construction site survey, SCAQMD staff has developed typical construction site scenarios for projects less than five acres that do not exceed the LSTs for any pollutant. A "typical" construction scenario means that the construction does not require additional activities such as major cut-and-fill for projects located on a hill or steep grade; or major soil excavation and hauling off-site for a project that includes sub-grade levels or parking; or demolition of buildings greater than 50 feet tall. A typical construction scenario may also include multiple story buildings, as they do not necessarily require additional equipment.

Multiple story buildings may simply require additional time (days) to complete construction. Lead agencies with proposed projects that involve construction of a multi-storied building can use the sample construction scenarios to directly represent the proposed project as long as the amounts and types of the construction equipment are consistent with those in the sample construction scenarios. Aside from these restrictions, the sample construction scenarios can be applied to any type of construction project, commercial, residential, educational, etc. (Table 1). Additional technical enhancements were made to update off-road and on-road emission factors based on ARB's Off-Road and EMFAC2002 models that will simplify emission calculations from off-road and on-road² equipment.

Future Enhancements

Staff welcomes input and feedback from interested parties for improving the accuracy of the construction scenarios. Staff will also consider developing additional construction scenarios that may be generally applicable to a range of different land use projects. SCAQMD staff is available to assist lead agencies or project proponents in addressing implementation issues.

For those parties interested in information on the methodology for deriving the LSTs, the reader is referred to the following document *Draft Localized Significance Threshold Methodology*. For additional information on analyzing air quality impacts in general, the reader is referred to the following available sources: *Handbook*, U.S. EPA's *AP-42*, or to California Air Resources Board's URBEMIS2002 model at the following internet address: http://www.arb.ca.gov/planning/urbemis/urbemis.htm.

SAMPLE CONSTRUCTION SCENARIOS

SCAQMD staff has prepared sample construction scenarios that generically represent a broad range of project types that occur in the district, e.g., commercial, residential, educational, etc., (Table 1). Each sample construction scenario is divided into five non-overlapping phases: demolition, site preparation, grading, building, and architectural coatings and paving. Based on actual construction equipment and activity (hours of operation, area disturbed, dirt and debris handled, etc.) obtained from the construction site surveys, the sample construction scenarios in Appendices A through E represent projects that do not exceed the most stringent localized significance thresholds identified in the mass emission look-up tables. The sample construction spreadsheets can be downloaded from the SCAQMD's http://www.agmd.gov/cega/hdbk.html. The most stringent localized significance thresholds represent the lowest allowable mass emissions for a pollutant from any SRA. In practice, if the lead agency calculates mass emissions from a proposed project, the resulting emissions should be compared to the appropriate mass rate look-up table based on the proposed project location (SRA), project size (area), and distance to the sensitive receptor.

For lead agencies that do not perform project-specific calculations or modeling to analyze localized air quality impacts, sample construction scenarios can be used based on the needs and/or air quality analysis expertise of the local lead agencies. The local lead agencies can use the sample construction scenarios to varying degrees including relying completely on the

² Emissions for a localized impact analysis would include only those emissions that occur on-site, such as watering truck travel, or haul/delivery truck travel through the site. Emissions from on-road vehicles off-site would not be included in a localized impact analysis; however, these emissions should be included in the regional impact analysis.

relevant sample construction scenario to represent the proposed project to selecting a sample construction scenario as a starting point for the air quality analysis and then modifying the equations or assumptions to fit site-specific characteristics of the project undergoing the environmental analysis. The following subsections describe the ways in which the sample construction scenarios might be used by local lead agencies.

1. Sample Construction Scenario Representative of Proposed Project – No Modification

If a proposed project is five acres or less and does not require additional construction activities such as major cut-and-fill, or excavation for sub-grade levels or parking, or demolition of a structure taller than 50 feet, the lead agency can use the applicable sample construction scenario to represent the emissions and impacts from the propose project instead of preparing a projectspecific construction air quality analysis. No additional quantification of construction emissions would be necessary. Using the sample construction scenario to represent the emissions and impacts from the propose project would allow the lead agency to conclude that localized air quality impacts during construction do not exceed any applicable LSTs in the mass rate tables. Like any other condition proposed in air quality analysis, if a lead agency decides to use a sample construction scenario to represent a proposed project, the lead agency would be required to ensure that actual project construction parameters generally are similar to, or less than, the construction parameters described in the sample project. Construction parameters include number of pieces and size of construction equipment, operating hours, area disturbed, dirt or debris handled, etc. To ensure that the sample construction scenarios are implemented, the lead agency could require the project proponent to adhere to the construction scenario as either part of the project description that is approved by the decision makers or as mitigation in an approved mitigation monitoring plan.

2. Sample Construction Scenario as a Basis for Estimating Emissions with Project Specific Information – Use of Scenarios as a template

In this situation, the lead agency wishes to establish project-specific construction scenarios for each construction phase. The lead agency would use the sample scenarios as templates or a basis to estimate project-specific emissions and analysis. The lead agency would calculate project-specific construction air quality impacts by using the same methodologies used to derive the sample construction scenarios, but tailoring them to fit the project-specific characteristics for the project under consideration. Lead agencies can download the spreadsheets used to derive the sample projects from the SCAQMD's website at http://www.aqmd.gov/ceqa/hdbk.html, and then use the spreadsheets to develop scenarios that fit their proposed project by changing the types, dimensions and numbers of equipment, workers, operation schedules, areas disturbed, dirt and debris handled, and trips described in the sample scenarios. Spreadsheet options that can be changed include the following:

- The number, rating, or load of equipment
- The number of workers
- The daily hours of use for equipment or operations
- The amounts of materials handled
- The size of the areas disturbed
- The dimensions of the structures demolished or built
- The mitigation measures or control efficiencies

- The lengths or number of trips
- The types of operations
- The emission equations or parameters used in the equations
- LSTs from project specific source receptor areas. Use the city of proposed project and the table in Appendix I to find the source receptor area of the proposed project, and then use the LST mass rate look-up tables to find the corresponding LSTs.

The shaded cells in the sample construction scenario spreadsheets are typical values that lead agencies may wish to modify using site specific parameters. The spreadsheets will automatically re-calculate results when the shaded cells are modified. Changing the values in the shaded cells will not affect the integrity of the worksheets. However, adding lines or entering values with units different than those associated with the shaded cells may alter the integrity of the sheets or produce incorrect results.

When modifying the spreadsheets lead agencies should consider the following issues:

- Verify that units of values entered are the same as the units associated to the cell. If the units do not match the equations will not calculate emissions correctly. Values should be converted to the same units as the cells in the spreadsheet before they are entered into the spreadsheet.
- If lines (rows) are added, verify that equations copied are referencing the correct cells. Use the text equation example or equations in other related Excel cells as an example. Also, verify that the summation cells are correct. If a line is added at the end of a series of rows, the summation cells may not include the added rows.
- After the individual phase spreadsheets are modified, verify that summary tables (spreadsheets) are referencing the correct cells.

For example, during the grading phase for a one-acre site the applicable sample construction scenario assumes that the following pieces of equipment would be used: a rubber tired dozer, motor grader, water truck, tractor/loader/backhoe, and haul truck. If the proposed project site requires only fine grading, then the lead agency could omit the haul truck (onsite) and haul truck offsite and adjust the hours of operation for the remaining pieces of equipment to calculate the maximum daily emissions for the proposed project. The amount and types of construction equipment are key parameters affecting construction emissions from a project. The emission results can then be compared to the applicable LSTs based on project size, receptor distance, and SRA.

3. Combined Representation and Template Analyses

When developing construction scenarios for the various construction phases, the local lead agency may conclude that some of the project construction phases closely match the sample construction scenario, while other construction phases are substantially different than the applicable sample construction scenario phase. In this situation the lead agency can apply a sample construction scenario phase to represent an applicable similar proposed project construction phase without further analysis. The same considerations described under the "sample construction scenario as representative of a proposed project" discussion apply here, that is, the construction project should be a "typical" construction project and the lead agency

should ensure that the representative sample construction scenario parameters are adhered to. For the construction phase scenarios that are substantially different than the sample construction scenarios, the lead agency may download the appropriate spreadsheets, customize the options as necessary, compile the emission results and compare the results to the applicable mass rate LST.

Conclusion

SCAQMD staff is available to assist lead agencies or project proponents in implementing the LST methodology and using the sample construction scenarios in an appropriate manner. If the air quality analysis results in emissions that exceed the applicable mass rate LST, feasible mitigation measures, if available, should be applied to the project. A number of potential mitigation measures are identified in Chapter 11 of the Handbook, which are also presented in Appendix H of this document.

CHAPTER 2

APPLYING THE SAMPLE CONSTRUCTION SCENARIOS

Application Summary Common Questions

APPLICATION SUMMARY

The sample construction scenarios were developed such that resulting emissions would not exceed the most stringent LSTs in the mass rate look-up tables. The most stringent localized significance thresholds represent the lowest allowable mass emissions for a pollutant from any SRA. In practice, if the lead agency calculates mass emissions from the proposed project, resulting emissions should be compared to the appropriate mass rate look-up table based on the proposed project location (SRA), project size (area), and distance to the sensitive receptor.

The sample construction scenarios were initially derived using construction estimator reference guides (e.g., Walkers, 2002; Richardson Engineering Services, 1996, Caterpillar Performance Handbook, 2002, etc.), which are used by contractors to bid for jobs. The scenarios were then revised based on the results of surveys conducted at active construction sites, which represent a variety of land use types (Table 1-1). In general, construction equipment and activity, hours of operation, and number of construction workers tend to be consistent across a wide variety of land Therefore, the sample construction scenarios would apply to land use types in addition to those listed in Table 1, as long as the structures to be constructed are similar in size and there are no additional construction activities such as major cut-and-fill for projects located on a hill or steep grade; major soil excavation and hauling off-site for a project that includes subgrade levels or parking; or demolition of buildings taller than 50 feet. Lead agencies for these unlisted land use types can use the sample construction scenarios to represent the proposed projects or as a basis to estimate emissions using project-specific information as part of the environmental analysis. Results can then be compared to the appropriate mass rate LST look-up tables. The following information is provided to assist the local lead agency with determining whether or not the sample construction scenarios can be used for their project and if the mass rate LST look-up tables can be used to determine localized air quality impacts.

COMMON QUESTIONS

What if the actual construction of the project does not exactly correspond to the sample construction scenario?

The sample construction scenarios were developed with information obtained at actual construction sites. As a result, it is expected that the sample construction scenarios would generally reflect construction equipment and activities used at construction sites for projects less than or equal to five acres, assuming the project does not include additional activities such as major cut-and-fill, etc. It is likely that during actual construction, a piece of equipment may occasionally need to operate for a couple of extra hours a day due to unanticipated contingencies. The sample construction scenarios may still be used in this situation as long as the additional operating hours were not expected to be required during the planning analysis or occur over an extended duration of time. It may be possible to allow one piece of equipment to operate additional hours routinely, if operation of other similar types of equipment is curtailed. This type of give and take should be explicitly described in the mitigation monitoring plan or project description if the sample project scenario parameters are included in the project description.

What is not acceptable is to routinely operate equipment substantially more hours per day than specified in the sample project scenario or use a greater number of pieces of equipment. This caveat applies to all construction phases. If it appears that the actual construction parameters

will be substantially different than those described in the sample construction scenario, then the contractor will need to work with the lead agency to identify ways to ensure that construction air quality impacts do not exceed the relevant mass rate LSTs. This may include limiting which pieces or types of equipment can be operated simultaneously, curtailing the total hours of operation of all or a portion of the construction equipment, applying additional mitigation measures, or replacing some equipment types with equipment with a smaller horsepower rating, etc.

What is a "similar" type project?

A similar type of project to those identified in Table 1 is a project that is generally the same size and is expected to have a similar construction schedule and activities as the types of projects presented in Table 1. Table 1 presents project types surveyed and that were used to develop the sample scenarios. The specific type of project (such as a shopping center, an apartment building, a service station, etc.) is not as important as the type and number of pieces of equipment, area disturbed, the amount of materials handled, and duration of each of the construction phases. The duration of each construction phase is of particular concern. The amount of work completed in a day is directly tied to the number and capacity of equipment available. The shorter the duration of a phase the more equipment is needed. Therefore, if a project is proposed to be completed in a shorter duration of time than presented in the sample construction scenarios, the number of pieces of equipment may need to be increased. Table 2 provides some general guidelines for determining if a project is similar to the sample projects.

Table 2
Shortest Phase Durations for Sample Projects^a

| Project Size (building square feet) | Demolition | Site Preparation | Grading | Building Construction | Coating and Paving |
|-------------------------------------|------------|---------------------|---------|--------------------------|--------------------|
| 1 Acre 40,000 sq ft structure | 10 Days | 1 Day | 2 Days | 2 Days | 2 Days |
| 2 Acre 87,000 sq ft structure | 20 Days | 2 Days | 4 Days | 3 Days | 5 Days |
| 3 Acre 124,000 sq ft structure | 20 Days | 3 Days | 6 Days | 3 Days ^b | 10 Days |
| 4 Acre 175,000 sq ft structure | 20 Days | 4 Days | 6 Days | 4 Days | 14 Days |
| 5 Acre 164,000 sq ft structure | 20 Days | 5 Days | 8 Days | 5 Days | 18 Days |

a) 1, 2, 3, and 5 acre parameters were estimated from survey information. 4 acre parameters were developed from information from the 1, 2, 3, and 5 acre sites.

What if my proposed project's emissions exceed an LST?

If a lead agency estimates emissions from a proposed project and the emissions exceed any LST in the sample construction scenarios, the lead agency may choose to compare the emission estimates to the appropriate mass rate look-up table based on location (SRA), project size (area), and distance to the sensitive receptor. Alternatively, the lead agency may consider refining emission estimates or applying mitigation measures to reduce proposed project emissions. See the following discussion. Lastly, the lead agency may decide to estimate concentrations at the

b) Interpolated value from 3 and 5 acre survey information.

receptors around the proposed project-site using an air dispersion model such as ISCST3. Lead agencies that choose dispersion modeling should follow the approach presented in the *Draft Localize Significance Threshold Methodology*.

How do I find the project specific LST?

The LSTs presented in the sample construction scenarios are the "worst-case" LSTs. The "worst-case" is the lowest allowable mass emission based on standard modeling meteorological data, the highest pollutant concentration measured at the nearest ambient air quality monitoring station over the past three years (or 10.4 micrograms per cubic meter for construction PM10 and 2.5 micrograms per cubic meter for operational PM10), and with receptors 25 meters or closer to the propose project site. LSTs are dependent on the proposed project acreage, ambient air quality, meteorological data, and distance to the receptor. The lead agency may choose use the emission calculations in the sample construction scenarios, but use the mass rate look-up tables to determine the LSTs for the source receptor area where the proposed project is to be located according to project size and distance to the sensitive receptor.

To find the LSTs for the source receptor area where the project is located, the lead agency would need to know the city where the proposed project would be located. The lead agency would use the table in Appendix I to find the source receptor area from the city where the proposed project would reside. Second, the lead agency would use the SRA to locate the LSTs from the mass rate LST look up tables by project acreage.

For example, a one-acre office building is proposed to be constructed in Pasadena, where the nearest receptor is 100 meters away. According to Appendix I, Pasadena is in Source Receptor Area 8 – West San Gabriel Valley. The LSTs associated with Source Receptor Area 8 (NOx = 134 pounds per day, CO = 925 pounds per day, and PM10 = 85 pounds per day) may be used in place of the "worst-case" LSTs presented in the sample construction scenarios. The regional significance thresholds are 100 pounds per day of NOx, less than 550 pounds per day of CO, less than 75 pounds per day of VOC, less than 150 pounds of SOx, and less than 150 pounds per day of PM10. The NOx and CO LSTs are greater than the regional significance thresholds of 100 pounds per day of NOx and 550 pounds per day of CO. The only LST that is more stringent than a regional significance threshold is the PM10 LST of 85 pounds per day of PM10 (the regional significance threshold is 150 pounds per day of PM10). To be considered less than significant, the proposed project may not exceed the localized significance thresholds and the regional significance thresholds. In this example, if PM10 emissions are less than 150 pounds per day, but exceed the localized significance threshold (85 pounds per day) the proposed project would be considered significant for localized PM10 air quality impacts.

What actions can be taken to reduce emission impacts by refining emission estimates?

The lead agency should determine which pollutants exceed the applicable LSTs and focus on refining emission estimates for those pollutants. The most restrictive LST is the PM10 LST, since the district is non-attainment for PM10. Therefore, it is likely that if the project exceeds an

The highest concentration over the last three years was used for all source receptor areas except for SRA 7 -East San Fernando Valley and SRA – 29 Banning Airport, because of nearby large single sources or events affecting the monitoring data. For these two source receptor areas the concentration for the last reported year (2003) was used.

LST, it would be the PM10 LST. It is possible that the proposed project may exceed more than one LST (e.g., PM10 and NOx).

Emission estimates can be refined by using more precise methodologies, emission factors or project specific parameters. The emission methodologies presented in the sample construction scenarios are generic methodologies developed by EPA, CARB and SCAQMD. Lead agencies can use alternative methodologies or emission factors to estimate emissions. However, the lead agency should reference any alternative methodologies and emission factors used, and provide sufficient documentation so that the public can easily follow the emission estimation.

The parameters presented in the sample construction scenarios are generic parameters developed by USEPA, CARB and SCAQMD. The lead agency may also substitute project specific parameters. For example, the silt content and moisture content used in the sample construction scenarios were taken from USEPA's AP-42. These values may be replaced by project specific silt content and moisture content. The maximum daily average wind speeds were developed by the SCAQMD from meteorological data across all source receptor areas. Lead agencies may use the maximum daily average wind speeds for the proposed projects specific source receptor area. Vehicle speeds, capacities and on-site distances traveled were based on assumption. Lead agencies may develop vehicle speeds, capacities and on-site distances based on project specific data. The amount of area disturbed, dirt and debris handled and equipment profiles were developed from construction surveys. Lead agencies may replace these parameters with project specific data.

In addition, lead agencies may also decide to adjust construction equipment hours, or the number or type of equipment on-site at any given time. Reducing the length of time certain pieces of equipment are used each day, amount of equipment operated each day, or the types of equipment that can be operated at the same time may reduce emissions. For example, if a project proponent requires both a bulldozer and a grader, but knows that neither will be on-site at the same time; the lead agency may estimate daily emissions for operations with bulldozer and graders separately. These two sets of independent emission estimates can then be compared separtely to the LSTs.

What actions can be taken to reduce emission impacts?

The lead agency should determine which pollutants exceed the applicable LST and focus on mitigation for those pollutants. The most restrictive LST is the PM10 LST, since the district is in non-attainment for PM10. Therefore, it is likely that if the project exceeds an LST, it would be the PM10 LST. It is possible that the proposed project may exceed more than one LST (e.g., PM10 and NOx).

The LST mass rate look-up tables do contain dust suppression techniques required by SCAQMD Rule 403. Rule 403 requirements must be met by all projects and are not considered mitigation. Therefore, the sample construction scenario emission estimates are considered unmitigated. A list of possible mitigation measures beyond Rule 403 requirements are presented in Appendix H of this document. The mitigation measures chosen by lead agencies should then be included in an approved mitigation monitoring plan.

What if the propose project acreage is between the project acreages on the LST mass rate look-up tables?

In this situation, the lead agency has two options. The first and easiest option would be to use the sample construction scenario and LSTs for acreage that is smaller than the proposed project. For example, if the proposed project is 2.5 acres, then use the two-acre sample construction scenario and LSTs.

The second option would be to develop LSTs from a ratio of the known LSTs for the smaller and larger acreages. For example, if the proposed project is 3.7 acres, then LSTs for 3.7 acres can be predicted from three and four acre mass rate LST look-up table values by a ratio of the areas. Appendix K contains a methodology for estimating the LSTs by linear regression.

If the second option is chosen, the sample construction scenario worksheets should be modified to reflect the 3.7-acre site. Either the three or the four acre sample construction scenario workbook can be used as a template. Each construction phase worksheet should be adjusted to reflect the 3.7 acre site. The structure dimensions in demolition and construction should be changed to project specific dimensions. The area disturbed in the site preparation and grading phases should be changed with project specific dimensions. The time length of each phase should be adjusted with project specific information. The amount of dirt and debris handled should be changed in the site preparation and grading phases. The truck trips and vehicle distance for trucks and bulldozers will change automatically when the area disturbed is changed in the site preparation and grading phases. The amount of demolition, debris handled, and truck trips in the demolition phase will change automatically when the size of the building is changed. The type and number of equipment, hours of operation and crew sizes should be adjusted with project specific information in each phase. If any of these values are not known, the lead agency may decide to approximate these values through linear regression from the three or four acre sample construction scenario values.

Lead agencies may chose to alter any other methodology, emission factor or parameter to better reflect the actual project characteristics.

What if a scenario for a larger project has more similarities to my project than the scenario for the actual size of my project?

The project proponent may use a larger scenario or phase of a larger scenario to represent their project. However, the project proponent would be required to compare the emission estimates from the larger scenario with the mass rate LSTs associated with the proposed project size. The lead agency would need to estimate emissions using site-specific parameters. The easiest method would be to modify the example scenario spreadsheets with project specific parameters. See the procedures outlined in the second method of using the sample construction scenarios under the Sample Construction Scenarios section in Chapter 1.

For example, if the amount of earth proposed to be moved in a two-acre project may be similar to the amount of earth moved in the three acre scenario, then the three-acre scenario can be used as a surrogate or modified with project specific information. The emissions from the sample scenario used to represent the proposed project or modified three-acre scenario would be compared to the two-acre mass rate LSTs, since the project is actually two-acres.

Why weren't the scenarios designed to be "worst-case" options maximizing emissions?

The sample construction scenarios were developed as average "worst-case" scenarios. SCAQMD developed parameters used in the scenarios from a construction site survey (see Pilot Study in Chapter 1 of this document). The survey provided information from approximately 50 sites, across SCAQMD jurisdiction, over a variety of project types. SCAQMD staff used the shortest number of days for phase completion (Table 2); and the upper ranges of areas disturbed, structure dimensions, areas paved, debris handled, etc. The average numbers of pieces of equipment, types of equipment, and operation hours were used. By using the shorter number of days per phase; the upper ranges of activities, areas disturbed and materials handled; and the average activity and number of pieces of equipment used an average "worst-case" was developed.

Since SCAQMD staff believes that the survey was representative of the projects under its jurisdiction and the average "worst-case" parameters were used to estimate emissions, few projects are expected to generate more emissions. Therefore, the emissions presented in the scenarios are likely "worst-case," since they represent actual construction activities.

It is difficult to develop the absolute "worst-case" scenario that has emissions that are only slightly below the LSTs, since there are many combinations of equipment, operation and material handling. SCAQMD staff developed one-, two- and five-acre scenarios for the October 2003 Governing Board Meeting based on "worst-case" parameters from building and construction estimators. The building industry stated that building and construction estimators use national averages that do not adequately represent Southern California. The use of survey data addresses the building industries' concerns.

Can the mass rate LST look-up tables be used to evaluate multi-storied structures?

Yes, in general the mass rate LST look-up tables can be used to evaluate multi-storied structures. Multi-storied structures were included in the construction survey. Demolition is directly related to structure size, since the amount of building debris handled is estimated from the volume of the building. Therefore, lead agencies should verify that the structure demolished is less than 50 feet tall as presented in the sample constructions scenarios. If the size of the proposed structure to be demolished, the amount and type of equipment is similar and the number of days spent demolishing the structure is equivalent or less, then the sample scenario can be used to represent the proposed project demolition phase. If the proposed project parameters are greater, the lead agency should modify the spreadsheets accordingly.

The size of the structure in the structure construction phase is not directly related to the emissions. The size of the structure is related to the amount and types of construction equipment used in the survey. However, if a project builds a larger structure using the same amount of equipment, the same amount of emissions should be generated. Therefore, the amount, types and operating hours of the equipment are more accurate predictors of emissions in the structure construction phase. Consequently, the lead agency should use the construction equipment parameters as a gauge to whether or not a proposed project can be represented by a sample construction scenario.

However, if the structure is multi-storied, because it includes below ground levels; the sample construction scenarios would not apply. The sample construction scenarios only consider dirt and debris hauling from grading and clearing operations. Excavation would require more equipment and more haul trips. Lead agencies or project proponents would be expected to estimate emissions for excavation.

Why do the scenarios use un-realistically large parameters?

Some of the parameters used in the sample construction scenarios are larger than those typically allowed by regulation or practice. For example, most planning commissions will not allow buildings to occupy the entire lot, but require a certain amount of parking, landscaping and sidewalks.

The survey forms were populated with check boxes to allow ease in completing the forms and to aid participants in completing the forms with the appropriate information in a prompt and consistent fashion. However, one disadvantage with using the check boxes was that for categories with large values ranges were used, such as building foot print, asphalt area, concrete area, area disturbed, dirt or debris handled, or distance traveled. Number of days each phase lasted, number of pieces of equipment, hours operated per day, and horsepower ratings were collected as discrete numbers. SCAQMD staff used the higher value in the range unless, the higher value was not appropriate. For example, one range for the building footprint is 41,000 to 60,000 square feet. However, one acre is approximately 43,000 feet. Therefore, if the proposed site is one acre then the maximum physical footprint area approximately 43,000 square feet. In practice, the city or county building codes may not allow a project proponent to build a structure that completely fills the site.

By using the upper limits of the ranges the emissions are conservatively estimated. Where these values are greater than allowed by city or county building code, the project emissions would likely be less than those in the sample construction scenarios. Since the sample construction scenario emissions are below the LSTs, projects that generate less emission than the sample construction scenarios would also be less than significant for construction emissions.

Why do the structure size and paving parameters appear to contradict each other?

The structure area on the one-, two-, and three- acre sample construction scenarios are approximately the same size as the site area; and the pavers are reported to operate six to eight hours per day. These parameters are consistent with the site area. However, as stated earlier, the parameters used to develop the sample construction scenarios were obtained from the construction survey. The parameters are the average "worst-case" values developed per phase not by project. Therefore, the "worst-case" structure construction might not have included paving and the "worst-case" paving phase might have included paving a site to be used as a parking lot. Therefore, it is not expected that all of the information between phases would be consistent. But, by using the average "worst-case" values, the sample construction scenarios should represent most proposed projects less than five acres in the SCAQMD's jurisdiction.

Where should the emission estimates and localized air quality impact analysis be presented?

The sample construction scenarios used to represent a proposed project, the modified spreadsheets or project specific analysis should be included as an attachment or appendix to the CEQA document. A detailed explanation of why the sample construction scenarios are appropriate to be used to represent the proposed project, or how the sample construction scenarios were modified with site specific information, or documentation of the project specific analysis should also be included. The explanation should present enough detail for other agencies or the public to understand what was done and why it was appropriate. A summary of the analysis and conclusions should be included in the text of the CEQA document.

Any additional mitigation or restrictions on activities or equipment should be clearly presented in the text of the CEQA document and in the mitigation monitoring plan.

What if I need further assistance?

Further assistance can be found by contacting the SCAQMD CEQA Section at (909) 396-3109 or submitting an e-mail to CEQA_admin@aqmd.gov.

EMISSION CALCULATION SOURCES

Off-Road Construction Equipment

Emission calculations for off-road equipment are based on emission factors provided by the California Air Resource Board (ARB) from their Off-Road Mobile Source Model, which can be downloaded from the SCAQMD website at http://www.aqmd.gov/ceqa/hdbk.html. The emission factors included in Appendix G represent a composite emission factor for each off-road construction equipment category in units of pounds of emissions per hour. These off-road emission factors will replace the emission factors in the SCAQMD CEQA Air Quality Handbook (CEQA Handbook), September 1993, Tables A9-8-A and A9-8-B.

The emission factors in Appendix G represent the overall fleet mix for the year specified, for each of the off-road construction equipment categories. The average horsepower and load factor

d) Interpolated value. Shortest duration in survey was 110 days.

are incorporated into each of the composite emission factors. Therefore, the equation for calculating combustion emissions from construction equipment is:

$$E_{pollutant} = EF_{polluant, year} \times T$$

Where

E_{pollutant} is the emissions per piece of construction equipment (pounds per day)

EF_{polluant, year} is the off-road emission factor for a specified piece of equipment for the pollutant

of concern for a specified year (See Appendix G for and example for 2005)

(pounds per hour)

T is the number of hours the equipment is operated on a daily basis (hours per day)

Emission factors for 2006 through 2020 may be downloaded from the SCAQMD web page at http://www.aqmd.gov/ceqa/handbook/offroadEF05_20.xls.

APPENDIX H - POSSIBLE MITAGATION MEASURES

MITIGATION MEASURE RESOURCES

The following are methods or techniques that may be applied to various operations or equipment when appropriate to mitigate estimated emissions.

Fugitive Dust Mitigation Measures

• SCAQMD, CEQA Handbook, Tables 11-4, page 11-15 and A11-9-A, page A11-77.

| Emission Source | Mitigation Measure | Emission Reduction Efficiency | Favorable Factors |
|--------------------------------|---|----------------------------------|--|
| Fugitive dust/ Construction | Apply non-toxic chemical soil stabilizers according to manufactures' specifications, to all inactive construction areas (previously graded areas inactive for ten days or more) | 30%-65%* | Stabilizers applied in sufficient concentration to provide erosion protection for at least on year |
| Fugitive dust/ Construction | Replace ground cover in disturbed areas as quickly as possible | 15%-49%* | Small, densely planted ground cover |
| Fugitive dust/ Construction | Enclose, cover, water twice daily, or apply non-toxic soil binders, according to manufactures' specifications, to exposed stockpiles (i.e., gravel, sand, dirt) with five percent or greater soil content | 30%-74%* | Automatic water mist or sprinkler systems should be installed in areas with stockpiles |
| Fugitive dust/ Construction | Water active sites at least twice daily | 34%-68%* | Water at sufficient frequency to keep soil moist enough so visible plumes are eliminated |
| Fugitive dust/ Construction | Suspend all excavating and grading operations when wind speeds (as instantaneous gusts) exceed 25 miles per hour | Not quantified | |
| Fugitive dust/ Construction | Monitor for particulate emissions according to District-specified procedures | Not quantified | |

| Emission Source | Mitigation Measure | Emission Reduction Efficiency | Favorable Factors |
|--------------------------|--|----------------------------------|---|
| Fugitive dust from roads | All trucks hauling, dirt, sand, soil or other loose materials are to be covered, or should maintain at least two feet of freeboard in accordance with CVC Section 23114, (freeboard means vertical space between the top of the load and top of the trailer) | 7%-14%* | Tightly secured covering to truck |
| Fugitive dust from roads | Sweep streets once a day if visible soil materials are carried to adjacent streets (recommend water sweepers with reclaimed water) | 25%-60%* | Sweep streets immediately after period of heaviest vehicular track-out |

| | | | activity |
|--------------------------|---|--|---|
| Fugitive dust from roads | Install wheel washers where vehicles enter and exit unpaved roads onto paved roads, or wash off trucks and any equipment leaving the site each trip. | 40%-70%* | Set up truck washing area on paved access road area so subsequent truck travel on unpaved roads can be eliminated |
| Fugitive dust from roads | Pave construction roads that have a truck volume of more than 50 daily trips by construction equipment, or 150 total daily trips for all vehicles | 92.5% (91% for trucks 94% for passenger vehicles) | |
| Fugitive dust from roads | Pave construction access roads at least 100 feet onto the site from main road | 92.5% (91% for trucks 94% for passenger vehicles) | |
| Fugitive dust from roads | Pave construction roads that have a daily traffic volume of less than 50 vehicular trips. | 92.5% (91% for trucks 94% for passenger vehicles) | |
| Fugitive dust from roads | Apply water three times daily, or non-toxic stabilizers according to manufacturers' specifications to all unpaved parking or staging areas or unpaved road surfaces | 45%-85%* | Use non-toxic chemicals that are formulated for unpaved road surfaces |
| Fugitive dust from roads | Traffic speeds on all unpaved roads to be reduced to 15 miles per hour or less | 40%-70%* | Effective traffic control |

 $^{^{*}}$ Use the lowest value if better information is not known. If higher than the lowest value is used, please provide the supporting analysis and data in the environmental documentation.

Combustion Emissions Mitigation Measures

Alternative Diesel Fuels

| Alternative Diesel Fuel | NOx | PM | НС | Toxics |
|---|------|-----|---|-------------|
| Aquazole fuel ^a | 16% | 60% | 25% lower than diesel vehicle emission standard | No Increase |
| Clean Fuels Technology - water emulsified diesel fuel ^b | 15% | 58% | 25% lower than diesel vehicle emission standard | No Increase |
| O ₂ diesel ethano-diesel fuel (O ₂ Diesel) ^c | 1.6% | 20% | 25% lower than diesel vehicle emission standard | No Increase |

EMISSION ESTIMATION METHODOLOGY FOR LST

- 1. **Divide project into phases.** The following provides a list of typical construction phases of a project.
 - Demolition
 - Site Preparation Clearing/Grubbing
 - Scraping/Grading
 - Trenching
 - Building construction
 - Architectural/asphalt paving/concrete paving
 - Operation

Notes: The above list represents typical construction phases, there may be phases of construction that are either not necessary for a project or that are necessary, but not identified on the list above. If one or more of the phases are not included in the project, there will be no emissions impacts. For example, for a project where construction will occur on vacant land, there would be no demolition phase, thus for the demolition phase of construction there would be no emissions impact. There may be, however, other construction phases that may be included such as filling or excavating that are not identified in the list above that should be included.

- 2. Estimate on-site NOx, PM10, and CO emissions for each of the construction phases identified. For each construction phase, the following on-site emission estimates are needed:
 - NOx, PM10, and CO combustion emissions from off-road construction equipment (such as bull dozers, tractors, loaders, cranes, etc.); and
 - PM10 fugitive dust emissions from construction activities.

Notes:

- Emission estimates for off-site on-road emissions are not needed for determining the significance for LST, however, these emissions are needed to determine of the project exceeds regional air quality thresholds.
- Estimates can be generated from design plans, contractor estimates, similar projects, URBEMIS2002, or construction estimators.

Example of emissions calculation for off-road construction equipment. Demolition phase:

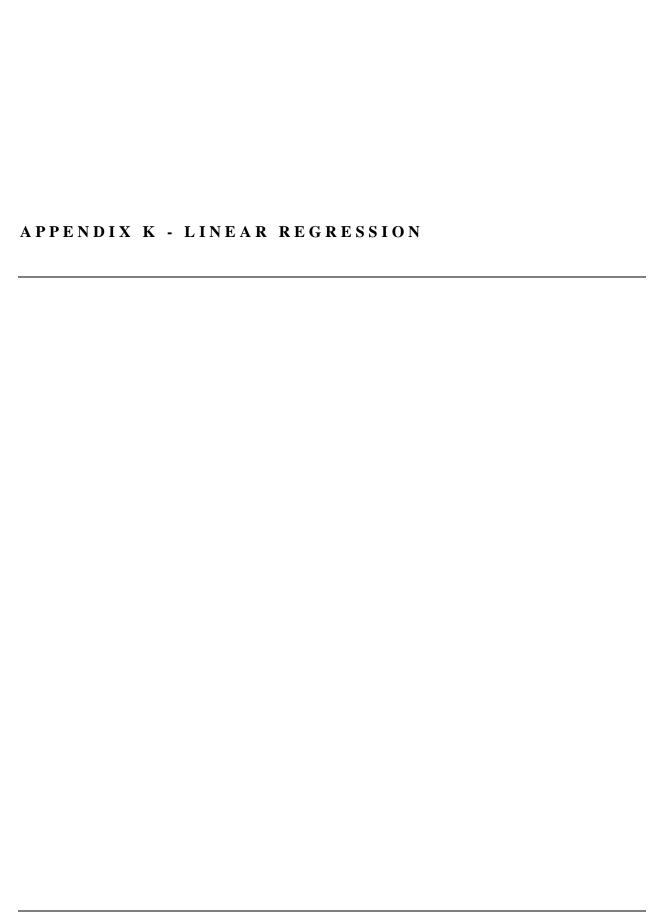

PM10 Demolition Emissions for 1 Acre Project

| Equipment | Number of Pieces | Emission Factor (pounds/hour) | Daily Operating Time (hours/day) | Emissions (pounds/day) |
|------------------------------------|---------------------|-------------------------------------|---|---------------------------|
| Concrete/Industrial Saw | 1 | 0.075 | 8.0 | 0.60 |
| Tractor/Loader/Backhoe | 2 | 0.086 | 8.0 | 1.38 |
| Rubber Tired Dozer | 1 | 0.123 | 1.0 | 0.12 |
| Total PM10 Combustion Emissions | | | | 2.10 |

NOx Demolition Emissions for 1 Acre Project

| Equipment | Equipment Pieces | Emission Factor (pounds/hour) | Daily Operating Time (hours/day) | Emissions (pounds/day) |
|----------------------------|---------------------|-------------------------------------|----------------------------------|---------------------------|
| Concrete/Industrial Saw | 1 | 0.825 | 8.0 | 6.60 |
| Tractor/Loader/Backhoe | 2 | 0.858 | 8.0 | 13.73 |
| Rubber Tired Dozer | 1 | 3.037 | 1.0 | 3.04 |
| Total NOx Emissions | | | | 23.37 |

- 3. For each construction phase, Compare estimated emission to significance thresholds.
 - Criteria pollutant mass emissions can be compared to regional significance thresholds found in Chapter 6 of the SCAQMD CEQA Handbook.
 - Criteria pollutant mass emissions can be compared to localized significance thresholds found on SCAQMD website http://www.aqmd.gov/hb/attachments/030736b.doc. Use the table in Appendix I to determine the Source Receptor Area from the city of the proposed project. Then use the Source Receptor Area to find the LSTs for the project on the mass rate LST look-up tables.
- 4. If emissions exceed significance thresholds develop mitigation measures. Mitigation measures can be found in Chapter 11 of the SCAQMD *CEQA Handbook* or documents provided by other agencies or organizations.

EXAMPLE PROBLEM

Estimate the PM10 mass rate LST for a 3.7 acre site from the three and four acre values in the Mass rate LST look-up tables.

Hand Calculation Method

PM10 LST from mass rate look-up tables

PM10 LST for a three acre site at 25 feet from the receptor = 7 pounds per day

PM10 LST for a four acres site at 25 feet from the receptor = 9 pounds per day

Linear Regession

$$y = a + bx$$

where,

$$a = Y - bX$$

 $b = [n\Sigma xy - (\Sigma x) (\Sigma y)]/[n\Sigma x^{2} - (\Sigma x)^{2}]$

n = number of pointsY = mean of y valuesX = mean of x values

therefore,

for
$$(3, 7)$$
 and $(4, 9)$

$$n = 2$$

$$Y = (7+9)/2 = 8$$

$$X = (3+4)/2 = 3.7$$

$$a = 8 - (2)(3.5) = 1$$

$$b = [2(57) - (7)(16)]/[2(25) - (7)^{2}] = 2$$

y = 1 + 2x = 1 + 2(3.7) = 8.4 pounds per day for a 3.7 acre site at 25 feet from the receptor

Excel Method

PM10 LST from mass rate look-up tables

PM10 LST for a three acre site at 25 feet from the receptor = 7 pounds per day

PM10 LST for a four acres site at 25 feet from the receptor = 9 pounds per day

Data Points Entered into Excel Worksheet

| | A | В |
|---|--------------|------------|
| 1 | x-value | y-value |
| | Area of Site | LST |
| | (acreage) | (mass/day) |
| 2 | 3 | 7 |
| 3 | 4 | 9 |
| 4 | 3.5 | |

Excel Formula

= FORECAST(x,known_y's,known_x's)

where, x =the data point for which you want to predict a value

known_y's = the dependent array or range of data known_x's = the independent array or range of data

= FORECAST(A4,B1:B2,A1:A2) or FORECAST(3.7,{7,9},{3,4})

= 8.4 pounds per day for a 3.7 acre site at 25 feet from the receptor
