

- Elevated methane concentrations (up to 58 ppm) were measured ~150-200 ft E of SS-25, probably from multiple naturally occurring holes on the side of the hill; SCAQMD inspectors used a portable TVA-1000 monitor to confirm these findings and complement the LICOR data; winds and methane concentrations were variable
- Increased methane concentrations (mostly in the 5-15 ppm range) were also measured ~200 ft NW of SS-25
- Videos were taken with FLIR cameras to identify the presence of natural gas
